Abstract. This paper describes various experiments done to investigate author profiling of tweets in 4 different languages – English, Dutch, Italian, and Spanish. Profiling consists of age and gender classification, as well as regression on 5 different personality dimensions – extroversion, stability, agreeability, openness, and conscientiousness. Different sets of features were tested – bag-of-words, text ngrams, and POS ngrams. SVM was used as the classifier. *Tfidf* worked best for most English tasks while for most of the tasks from the other languages, the combination of the best features worked better.

Keywords: author profiling, tfidf, normalized term frequency, SVM, POS, ngrams

1 Introduction

Author profiling has been of importance in the recent years. From a forensic standpoint for example, it could be used to determine potential suspects by getting linguistic profiles and identifying characteristics. From a business intelligence perspective, companies could target specific people through online advertising. By knowing the profile of the authors, companies would easily find what a specific group of people talk about online and devise strategies to advertise to these people. They could also analyze product reviews and know what types of products are liked or disliked by certain people.

The growth of the internet where text is one of the main forms of communication is one of the reasons for a rising interest in author profiling. Through this growth, various corpora could be extracted, curated, assembled from different sources such as blogs, websites, customer reviews, and even twitter posts. Of course, this presents some problems. For example, people from different countries who use the same online platform such as Twitter or Blogger could behave differently in terms of text usage. This presents a difficulty in profiling. This work tries to take this difficulty into account by studying which kind of features are useful for different languages.

The aim of this work is to investigate the dataset given in PAN 2015 [12] where twitter data from 4 different languages are used to profile an author based on age, gender, and 5 personality traits - agreeability, conscientiousness, extrovertedness, openness, and stability. The four languages are English, Dutch, Italian, and Spanish. There are three different sets of features that are investigated in this work. The first set is the bag of words features in the form of term frequency and term frequency inverse document frequency. The second set are text ngrams. And finally, we also study part of speech ngrams to see if information extracted from these features are useful for characterizing twitter users.

2 State of the Art

One of the first few works on author profiling is that of Argamon et al. in [1] where texts are categorized base on gender, age, native language, and personality. For personality, only neuroticism was checked. The corpus comes from different sources. The age and gender have the same corpus taken from blog postings. The native language corpus was taken from International Corpus of Learner English. Personality was taken from essays of psychology students from University of Texas in Austin. Two types of features were obtained: content-based features and style-based features and Bayesian Multinomial Regression was used as a classifier. Argamon et al. had some interesting results where from the gender task, they were able to achieve 76.1% accuracy using style and content features. For age task with 3 classes, the accuracy was at 77.7% also using style and content features. For the native language task, the classifiers were able to achieve 82.3% using only content features. And finally, in checking for neuroticism, the highest obtained was 65.7% using only style features.

There has also been some research that uses datasets collected from social media. A particular example is that of Schler et al. in [14] where writing styles in blogs are related to age and gender. Stylistic and content features were extracted from 71,000 different blogs and a Multi-Class Real Winnow was used to learn the models to classify the blogs. Stylistic features included parts-of-speech tags, function words, hyperlinks, and non-dictionary words. Content features included word unigrams with high information gain. The accuracy achieved was around 80% for gender classification and 75% for age identification.

The work of Argamon et al. [1] became the basis for the work in PAN. It is an ongoing project from CLEF with author profiling as one of its tasks. It currently has three editions. In the first edition of PAN [11] in 2013, the task was age and gender profiling for English and Spanish blogs. There were a variety of methods used. One set includes content-based features such as bag of words, named entities, dictionary words, slang words, contractions, sentiment words, and emotion words. Another would be stylistic features such as frequencies, punctuations, POS, HTML use, readability measures, and other various statistics. There are also features that are n-grams based, IR-based, and collocations-based. Named entities, sentiment words, emotion words, and slang, contractions and words with character flooding were also considered. After extracting the features, the

classifiers that were used were the following - decision trees, Support Vector Machines, logistic regression, Naïve Bayes, Maximum Entropy, Stochastic Gradient Descent, and random forests. The work of Lopez-Monroy in [4] was considered the winner for the task although they placed second for both English and Spanish with an accuracy of 38.13% and 41.58% respectively. They used second order representation based on relationships between documents and profiles. The work of Meina et al. [7] used collocations and placed first for English with a total accuracy of 38.94%. On the other hand, the work of Santosh et al. in [13] gave a total accuracy of 42.08% after using POS features for Spanish.

In PAN 2014 [10], the task was profiling authors with text from four different sources - social media, twitter, blogs, and hotel reviews. Most of the approaches used in this edition are similar to the previous year. In [3], the method used to represent terms in a space of profiles and then represent the documents in the space of profiles and subprofiles were built using expectation maximization clustering. This is the same method as in the previous year in [4]. In [5], ngrams were used with stopwords, punctuations, and emoticons retained, and then idf count was also used before placed into a classifier. Liblinear logistic regression returned with the best result. In [17], different features were used that were related to length (number of characters, words, sentences), information retrieval (cosine similarity, okapi BM25), and readability (Flesch-Kincaid readability, correctness, style). Another approach is to use term vector model representation as in [16]. For the work of Marquardt et al. in [6], they used a combination of content-based features (MRC, LIWC, sentiments) and stylistic features (readability, html tags, spelling and grammatical error, emoticons, total number of posts, number of capitalized letters number of capitalized words). Classifiers also varied for this edition. There was the use of logistic regression, multinomial Naïve Bayes, liblinear, random forests, Support Vector Machines, and decision tables. The method of Lopez-Monroy in [3] gave the best result with an average accuracy of 28.95% on all corpus-types and languages.

3 Dataset and Tools

The data set was taken from PAN 2015 Author Profiling task [9]. It is composed of a set of tweets for 4 different languages - English, Dutch, Italian, and Spanish. It was decided to build a different model for each profiling element: age, gender, and the 5 different personality traits - extroverted, stable, agreeable, open, conscientious. There were 4 categories for the age classification - 18-24, 25-34, 35-49, and 50 and above but for Dutch and Italian, age classification is not possible because there was no data given. For personality traits, the values range from -0.5 to 0.5.

The number of given users varies for each language. There were 152 users for English, 34 for Dutch, 38 for Italian, and 100 for Spanish. Each user has different number of tweets. The dataset is balanced based on gender.

Processing the data was done through Python using the scikits-learn [8] library. For POS tags, TreeTagger as described in [15] was used with a python wrapper.

4 Methodology

For this study there were three sets of features that were placed under study - bag-of-words features, text ngrams, and part of speech tags. The same approach was used for all the tasks which was more or less straightforward: feature extraction, then use the features for either classification or regression, and the evaluation was made through a 10 fold cross validation.

There were four main experiments. The first one uses two different bag of words features separately - normalized term frequency and *tfidf*. The second one tries two text ngram features separately - text bigrams and text trigrams. The third one uses three POS ngrams features - POS unigrams, POS bigrams, and a combination of POS unigrams and bigrams. Accuracies and mean squared errors were noted and the feature that gave a better result in each type were also noted. A comparison between each type was done by using the Wilcoxon signed rank test [18] to check if the difference between the feature types are significant or not. It was used among the other tests because it allows the comparison between two experiments done on the same data set without making any assumptions on the distributions from which the set is drawn. A confidence interval of 95% was used.

After noting which features were the best among each category, these features were then concatenated and used for another classification for the final experiment. The following subsections gives the details for preprocessing, the features extracted, and the learning algorithm.

4.1 Preprocessing

For each language, xml files from each user are read. Then the tweets taken from each user are extracted and concatenated into one line to form one training example. The examples are then transformed by putting them all in lower case. No stop words are removed. Hashtags, numbers, mentions, shares, and retweets were not processed or transformed to anything else. The resulting file is used for feature extraction.

4.2 Feature Extraction

The following set of features were extracted after preprocessing and the number of features extracted from each set is given in the table 1:

Bag-of-Words Two different bag-of-words features were extracted. The first is normalized term frequency. Terms are normalized by the number of terms

Feature	English	Dutch	Italian	Spanish
tf	26264	8569	12590	24688
tfidf	26264	8569	12590	24688
Text bigrams	104435	29648	36002	87313
Text trigrams	147577	39286	44051	122130
POS unigrams	35	39	38	68
POS bigrams	895	792	443	1999

Table 1. Number of features extracted

in a training example. No terms were discarded. The second one is *tfidf* where terms were normalized by the inverse document frequency. No terms were also discarded.

Text Ngrams Text ngrams were the second set of features that was examined. Counts of bigrams and trigrams were taken after preprocessing. No normalization was done and no terms were discarded.

POS Ngrams Part of speech tags were also another set of features that was examined in this study. It was extracted by using a python wrapper to Schmid’s TreeTagger program as detailed in [15]. Counts for unigrams, bigrams, and the combination of the two were used as features. The English parameter file for TreeTagger has 36 different tags. Italian has 38 tags. Dutch has 41 and Spanish has 75. No terms were discarded.

4.3 Learning algorithm

The learning algorithm used was a Support Vector Machines [2] with a linear kernel and the parameter C chosen to be 1, which was the default setting. No parameter tuning was done in these experiments. The rationale for such is because the goal was to determine the effects of the features to the classification and regression.

4.4 Performance metrics

Accuracy was the metric used for the age and gender task. On the other hand, mean squared error was used for all problems involving personality. The mean squared error is given in equation 1.

$$MSE = \frac{1}{n} \sum_{i=1}^n (y_{pred} - y_{actual})^2 \quad (1)$$

The objective is to get the maximum accuracy and to get the minimum squared error.

5 Experimental results

The following subsections details the results for the different features given each task. The values in boldface are the highest among within each type. However, it does not convey statistical difference in comparison to other values of the same feature type or even compared to all the other values in the column. Values in the last row may be in boldface as well if the result is better than any of the results from the different features.

5.1 Age Classification

The result for age classification is given in table 2. *Tfidf* and text bigrams gave the better result among bag of words features and text ngrams respectively. For POS ngrams however, bigrams for English gave the best result while the combination of unigrams and bigrams gave a best result for Spanish. Looking at the statistical difference, only the results from bag of words features for English and text ngrams for Spanish were different from each other. Looking at the columns, we can see that *tfidf* features gave an accuracy of 69.1% for English. It is higher than the normalized term frequency and even the combination of the best features. For Spanish however, the combination of the best features gave the highest accuracy of 72.0%. Dutch and Italian dont have results since the data set doesnt have any labels on this aspect.

Feature		English	Dutch	Italian	Spanish
BoW	tf	0.395			0.460
	tfidf	0.691			0.470
Text Ngrams	bigrams	0.638			0.640
	trigrams	0.553			0.460
POS Ngrams	unigrams	0.579			0.550
	bigrams	0.611			0.670
	uni+bi	0.593			0.700
	combo	0.650			0.720

Table 2. Age classification results

5.2 Gender Classification

The result for gender classification is given in table 3. *Tfidf* features gave the better results over normalized term frequency. Text trigrams worked better than text bigrams for English and Dutch. On the other hand, text bigrams work better for Italian and Spanish. Finally, the combination of POS unigrams and bigrams worked better for English, Italian, and Spanish, but POS unigrams worked better for Dutch. Looking at the statistical difference, only the results for text ngrams for Spanish, and bag of words for English and Spanish were different. Looking

at the columns, *tfidf* gave the highest accuracy result for English tweets with 68.3%. However for the other languages, the combination of the features gives the best result - 65.8% for Dutch, 75.8% for Italian, and 80.0% for Spanish. Only Italian has a tie with another feature set - combination of POS unigrams and bigrams.

Feature		English	Dutch	Italian	Spanish
BoW	tf	0.511	0.450	0.617	0.550
	tfidf	0.683	0.517	0.750	0.690
Text Ngrams	bigrams	0.623	0.550	0.733	0.700
	trigrams	0.652	0.650	0.700	0.520
POS Ngrams	unigrams	0.659	0.642	0.733	0.770
	bigrams	0.659	0.567	0.733	0.750
	uni+bi	0.660	0.592	0.758	0.780
	combo	0.671	0.658	0.758	0.800

Table 3. Gender classification results

5.3 Personality Regression

The results for personality regression are given in tables 4, 5, 6, 7, and 8. For the extroversion component of the personality as seen in table 4, we see that *tfidf* works better than normalized term frequency for all languages. Text bigrams also work better than trigrams. POS bigrams work better for Dutch, Italian, and Spanish. POS unigrams worked better for English. However, looking into statistical difference among features within a class, only results from Spanish that uses POS unigrams were statistically different from POS bigrams or the combination. Looking at the columns, the combination of all the best features gave the best results for Dutch, Italian, and Spanish. However, *tfidf* gave the best results for English.

Feature		English	Dutch	Italian	Spanish
BoW	tf	0.027	0.024	0.030	0.029
	tfidf	0.023	0.016	0.019	0.025
Text Ngrams	bigrams	0.025	0.015	0.021	0.025
	trigrams	0.026	0.018	0.022	0.028
POS Ngrams	unigrams	0.040	0.020	0.030	0.129
	bigrams	0.047	0.015	0.015	0.023
	uni+bi	0.050	0.016	0.017	0.024
	combo	0.029	0.014	0.015	0.022

Table 4. Extroversion regression results

The results for the stability component of personality are given in table 5. The results vary for each language. *Tfidf* features work well for English with a mean squared error of 0.039. The combination of POS unigrams and bigrams work well for Dutch and Italian. But for Italian, the POS bigrams also work just as well as the combination. Finally for Spanish, POS bigrams gave the best results.

Looking into statistical difference among features within a class, results from Italian and Spanish that uses POS unigrams were statistically different from POS bigrams or the combination. Results from bag of words features for Spanish were also statistically different from each other.

Feature		English	Dutch	Italian	Spanish
BoW	tf	0.048	0.048	0.031	0.046
	tfidf	0.039	0.028	0.030	0.034
Text Ngrams	bigrams	0.045	0.031	0.031	0.038
	trigrams	0.048	0.041	0.033	0.041
POS Ngrams	unigrams	0.055	0.030	0.040	0.135
	bigrams	0.057	0.027	0.020	0.032
	uni+bi	0.059	0.023	0.020	0.033
	combo	0.044	0.027	0.023	0.034

Table 5. Stability regression results

The results for the agreeability component of personality are given in table 6. For this set, *tfidf* seems to work for English, Dutch, and Spanish, except that Spanish *tfidf* results tie with results from the combination of the best features. The combination of the best features also works well for Italian. Looking into statistical difference among features within a class, only results from Spanish that uses POS unigrams were statistically different from POS bigrams or the combination.

Feature		English	Dutch	Italian	Spanish
BoW	tf	0.025	0.025	0.026	0.028
	tfidf	0.023	0.024	0.022	0.024
Text Ngrams	bigrams	0.027	0.030	0.026	0.027
	trigrams	0.026	0.026	0.026	0.028
POS Ngrams	unigrams	0.031	0.041	0.039	0.222
	bigrams	0.037	0.034	0.020	0.027
	uni+bi	0.038	0.036	0.024	0.029
	combo	0.028	0.031	0.019	0.024

Table 6. Agreeability regression results

The results for the openness component of personality are given in table 7. It again shows varied results. *Tfidf* features gave the best results for English. The combination of POS unigrams and bigrams also tied with *tfidf* gave the best results for Dutch. For Italian however, three different feature sets gave the same results - POS bigrams, the combination of POS unigrams and bigrams, and finally, the combination of the best features. Finally for Spanish, POS bigrams gave the best results. Looking into statistical difference among features within a class, bag of words features for Spanish were statistically different. Also, results from Spanish that uses POS unigrams were statistically different from POS bigrams or the combination.

Feature		English	Dutch	Italian	Spanish
BoW	tf	0.023	0.019	0.015	0.036
	tfidf	0.020	0.012	0.014	0.026
Text Ngrams	bigrams	0.021	0.014	0.015	0.030
	trigrams	0.022	0.015	0.016	0.034
POS Ngrams	unigrams	0.029	0.016	0.019	0.061
	bigrams	0.035	0.013	0.013	0.023
	uni+bi	0.038	0.012	0.013	0.024
	combo	0.024	0.013	0.013	0.024

Table 7. Openness regression results

The results for the conscientiousness component of personality are given in table 8. We again have varied results, POS bigrams and the combination of POS unigrams and bigrams gave the best results for English. The combination of the best features gave the best results for Dutch. POS bigrams gave the results for Italian while *tfidf* gave the best results for Spanish. Looking into statistical difference among features within a class, results from Spanish that uses POS unigrams were statistically different from POS bigrams.

Feature		English	Dutch	Italian	Spanish
BoW	tf	0.023	0.015	0.024	0.028
	tfidf	0.018	0.012	0.022	0.024
Text Ngrams	bigrams	0.019	0.012	0.022	0.026
	trigrams	0.020	0.015	0.023	0.028
POS Ngrams	unigrams	0.019	0.061	0.027	0.083
	bigrams	0.013	0.023	0.015	0.028
	uni+bi	0.013	0.024	0.017	0.033
	combo	0.019	0.010	0.016	0.025

Table 8. Conscientiousness regression results

6 Conclusions and Future Work

From the current work, we can observe that different features work better for different languages. *Tfidf* features worked best for all profiling tasks in English except conscientiousness regression. The combination of the best features gives better results for gender classification and extroversion regression for Dutch. However, other features work better for the other tasks - POS unigrams and bigrams for regression on stability, *tfidf* on agreeability and openness, POS unigrams and bigrams also for openness, and the combination of the best features for conscientiousness. Two types of features gave the best results for the different tasks for Italian - the combination of all the best features and the combination of POS unigrams and bigrams. Finally for Spanish, the combination of all the best features works for most of the tasks - age and gender classification and extroversion and agreeability regression. POS bigrams worked best for stability and openness regression, while *tfidf* worked best for conscientious regression.

These results are by no means exhaustive. There are still many methods that could be explored. For instance, the preprocessing is quite minimal. More features could be extracted from the text such as number of links, retweets, hash-tags, and mentions, length of tweets, ratios of uppercase to lower case characters, non-dictionary words, lexical diversity, emoticons, sentiment words, informative words and character ngrams. Furthermore, since Support Vector Machines with linear kernel was used, it would also be worth exploring other kernels as well as doing parameter tuning. Finally, a multi-dimensional classification approach can also be explored. Instead of having two distinct classes for age and gender classification for instance, the target classes could be the combination of the two classes. Instead of having 5 different regressions on personality traits, it would be possible to take all 5 traits all at once. This is worth exploring since the traits can be codependent.
